Figure 1: Structure-based alignment of human cytochrome P450 3A4 with bacterial P450 crystal structures, and rabbit P450 2C5.

Sequence numbering is indicated for each enzyme. This alignment is first based on the structural alignment of bacterial P450s and rabbit P450 2C5 derived from GOK
50 analysis. Human P450 3A4 sequence was then aligned with in-house tool (SmartConsAlign) that locates the CSBs on the target sequence, without introduction of any structural information for this complex. The alignment shown outside the CSBs is thus not relevant. The CSB sequences are indicated by bold uppercase characters and are highlighted in yellow. Amino acids strictly conserved
55 between CYP3A and 2C5, or between CYP3A and all the sequences of crystal structures, are highlighted in blue.

Figure 2: Ramachandran plot of a lowest energy model produced by DYANA-XPLOR calculations from the six-template structural alignment.

**Figure 3: view of one optimized CYP3A4 model. This figure can be replaced by
5 the whole set of coordinates file in the PDB format)**

Figure 4: final position of testosterone after soft-restrained restrained dynamics docking.

10 Figure 5: Energy profile of the soft-restrained restrained dynamics docking of testosterone into CYP3A4 model.

Example 1: Determination of the 3D-structure of P450 3A4.

15

Material

The coordinates of the six P450 crystal structures: P450cam (3cpp), P450terp (1cpt), P450BM-3 (2hpd), P450eryF (1oxa), P450 nor (1rom) and P450 2C5 (1dt6) were retrieved from the Brookhaven Protein data bank. The structural alignment
20 and the conserved regions determination were realized using the GOK software (Jean et al. 1997) running on an Octane Silicon-Graphics workstation. Structures were built using the DYANA (Güntert et al. 1997), and X-PLOR softwares (Brünger 1992). Docking studies were performed with SYBYL 6.6 (Tripos Inc.). The structures were analyzed using Procheck-NMR (Laskowski et al. 1993) and
25 visualized under SYBYL 6.6 (Tripos Inc.).

Common Structural Blocks (CBS) determination.

The first key point of this homology modeling study is the identification of the structural elements (hereafter designed as CSBs for Common Structural Blocks)
30 conserved among the family of cytochromes P450 of known 3D structures, and the localization of these elements in the target sequence. These two tasks are performed using the GOK software (Jean et al. 1997), and are well described in a forthcoming article (Minoletti et al., *Proteins, Structure, Function and Genetics*, 2002). In brief,

the basic idea of CSB identification by GOK is to use an internal coordinate representation – (α, τ) in our case (another representation of ϕ, ψ angles) – and to search for fragments in the six-template proteins having similar local trajectories in the internal coordinate space. GOK provides two adjustable parameters (the α -mesh
5 and the α -margin) that define the tolerance on the comparison of the trajectories. These parameters were adjusted recursively to values ranging from 15 to 30° (α -mesh) and 1 to 3 (α -margin in mesh units). The evaluation of the quality of the match was measured using two multiple-way rmsd calculated in the cartesian coordinates space: mp-rms (the mean of all pairwise rms deviations) and s-rms (the
10 mean of the deviations calculated with respect to a mean structure obtained from the average internal coordinates). For the different CSBs, mp-rms value ranged between 0.3 and 4.9 Å in average, and s-rms between 0.04 and 2.4 Å.

CYP3A4 sequence alignment and evaluation of the profile

15 The multiple sequence alignment derived from the CSB identification was then used to build a similarity profile. The profile is defined as a position-specific scoring table created from aligned gap-free segments such as CSBs (Jean et al. 1997). The alignment then consists in a search of the best match (as per the best score) between a CSB of sequences defined structurally (*i.e.* independently of the
20 nature of the aligned residues) and several other sequences that are well-aligned and exhibit a high sequence similarity. In the P450 3A subfamily, many proteins exhibit high sequence similarity. We extended our profile search program to take this information into account, *i.e.* to align the profile with a pre-defined multiple alignment of the cytochromes P450 3A subfamily members sequences (Gotoh 1992;
25 Nelson et al. 1996). The similarity score was calculated using BLOSUM62 matrix (Henikoff and Henikoff 1992; Loiseau 2002). The in-house tool SmartConsAlign (Atelier de Bio-informatique, Université Paris VI, <http://www.wabi.snv.jussieu.fr/~jompo>) allows to move the consensus matrix along the multiple sequence alignment of P450 3A family, and computes for each position
30 a score of similarity. The best alignment found of CYP3A4 on CSBs is shown in Figure 1 (Loiseau 2002).

Once the alignment is completed, the 3D model rebuilding process can incorporate the atom Cartesian coordinates of the template structures only for amino acids located in structurally conserved regions (*i.e.* the CSBs). The coordinates of any of the template structures can be used for the final template. In each CSB, amino acid positions have been renumbered according to the sequence of human P450 3A4. At a given position, when residues are identical between all the template structures and the target sequence, the 3D coordinates of the reference residues are purely assigned to the modeled (target) residue. When residues differ, only the coordinates of the backbone atoms are assigned ($C\alpha$), and sometimes $C\beta$ when they exist. Side chains are rebuilt from databanks giving the most probable rotamers for each amino acid (see below). In some cases, it was possible to superimpose the positions of carbon atoms of lateral chains up to ranks γ and δ , thus explicitly defining a unique rotamer.

For amino acids located outside the CSBs (structurally variable zones that include generally loops), the rebuilding is more complex, and can be done only after structurally conserved zones rebuilding. In the multiple structural alignment (fig. 1), the regions separating the CSBs bring no structural information at all. Short loops are rebuilt entirely, since solutions of acceptable geometry for atoms are in limited number, *i.e.* the lowest energy drives the selection of the good geometry. For longer segments, various structures are provided by the constrained minimization runs, and a manual selection is operated.

Constraints derivation and rebuilding

A strategy inspired of the techniques commonly used to built structures from NMR data (Patard et al. 1996) is applied. The main idea is to express all available information issued from the comparison of the templates in term of geometrical constraints (distances and angles). Each constraint will be defined as an interval (for a given pair of atoms, this is the average of the six atom-atom distances found in the template structures +/- the standard deviation), similarly to the strategy developed by Havel and Snow (Havel and Snow 1991). However, the number of constraints corresponding to all atom-atom distances, for example, would be prohibitive for a protein of the size of the P450 (around 1,000,000 inter-residual distances if we consider 250 conserved residues and four atoms by residues). Previous NMR

studies (Patard et al. 1996) have shown that local constraints are sufficient to allow a correct reconstruction of a structure. This reduces drastically the number of constraints needed, and increases the flexibility of the model. In addition, similarly to what is done in NMR, we can build a family of structures instead of a single model. This allows an easier analysis of the well or less well-predicted regions. This is also an advantage for the analysis of the side-chain positions, particularly in prevision of a substrate docking study. Finally, The loops are passively reconstructed with the rest of the structure. The only specific information we have introduced in variable regions was to guide all their residues to an allowed region of the Ramachandran diagram. Indeed, analysis of well-defined structures shows that nearly all residues, including those of the loops, should belong to an allowed region. The better the structure is, the lower the proportion of residue outside the allowed region. This criterion of quality has been applied to derive the model described herein.

Accordingly, we retained for model rebuilding all the distance and angle intervals corresponding to the following principles:

- all distances for which the lower bondary was less than 8 Å. This cutoff is totally sufficient to ensure, at least, the formation of the local structure elements. Such a cutoff is relatively high and thus costly in terms of size of constraints file, but proved necessary to ensure good results for the P450s. This may be due to the fact that P450 enzymes are mostly formed of α -helices, the average distance between two helices being larger than between two adjacent β -strands. In addition, the percentage of residues located outside CSBs is rather high in the structural alignment of P450s, and a better convergence can be obtained only at the expense of a high number of rebuilding distance constraints.
- all the distances involving at least one side-chain atom, to preserve the spatial arrangement between CSBs
- finally, all the distances involving atoms of the heme group, to fix as much as possible the neighborhood of the iron atom.

The total number of distance constraints was, in these conditions, equal to 58506 (Table 3).

Similarly, angular constraints were calculated in each building block. A CSB is indeed defined as a conserved trajectory in the ϕ, ψ coordinates space (or α, τ). Thus, dihedral angles ϕ and ψ of all residues located in CSBs can be defined as constraints, given by the average values of corresponding ϕ, ψ angles in the six
5 templates +/- the standard deviation. To these backbone dihedral angles, can be added the side chains torsion angles χ_1, χ_2 whenever possible, as determined by the rotamer selection. The total number of dihedral angle constraints was, in these conditions, equal to 761 (Table 4).

10 *Rotamer selection*

In proteins, the preferential orientation of the side chain ($60^\circ, -60^\circ, 180^\circ$) depends on the local conformation of the residue, and thus on the nature of the secondary structure in which the residue is involved. According to the rotamer library built by Karplus and coll. (Dunbrack and Karplus 1993), to a given (ϕ, ψ) couple in the
15 Ramachandran diagram can be associated a specific rotamer. These tables have been used to determine the most probable rotamer for each residue located in CSB, except when there are conserved atoms in the side chain that assign unambiguously a rotamer (χ_1, χ_2) . The selected (χ_1, χ_2) couples are reported in the dihedral constraints of Table 4.

20

Structure calculation and optimization

We used a procedure similar to structure calculation starting from NMR constraints. A first set of structures was calculated using the DYANA software (Güntert et al. 1997) and the two constraints Tables 4 and 3. It must be pointed out that these
25 Tables represent the scaffold for rebuilding any of the CYP3A that can be aligned (Figure 1). Families of structures are generated. The energy of each structure is minimized with the procedure vtfmin in DYANA.

Due to the size and the amount of loops in the molecule, some structures presented topological defects and were discarded. The others were further optimized by using
30 the X-PLOR software. A set of constraints was added at this stage in order to guide the loop residues to the nearest allowed region in the Ramachandran diagram. The

topology and parameter files of CHARMM22 were used. The electrostatic term was turned off.

The DYANA software is unable to deal with disconnected objects. A new residue type was, thus, added to the standard amino acid library to take into account the presence of the heme. This residue was obtained by combining the heme to a
5 cysteine and was inserted at position 441 in the sequence of the protein (Figure 1).

Description of the CYP3A4 Model

10 We rebuilt a model of the protein depleted of its first 50 residues (N-terminal domain). This segment is highly hydrophobic, and supposed to form the anchor of the protein in the membrane. There is no structural information about this putative transmembrane domain, and this segment was thus not incorporated into the modeling process, and in the final model. Such a “free” segment (with no
15 constraints) would perturb the convergence of computation or the stability of the whole rebuilt structure.

The quality of the various structures optimized under XPLOR was checked for the stereochemical quality (backbone and side chain conformation) by PROCHECK
20 (Laskowski et al. 1993). The Ramachandran plot shows that our six-template approach generated converging models, possessing the same fold. The lowest energy models had 73% of their non-glycine and non-proline residues with ϕ , ψ conformation in the most favoured regions of the Ramachandran plot (core region), 20% in additional allowed regions, and 5% in the generously allowed regions. Only
25 2.3% (9 residues) had their ϕ , ψ conformation in disallowed regions (Figure 2). The total number of residues in the model is 452; which 399 are non-glycine and non-proline residues, and number of residues in the native sequence is 502.

When compared to the CYP2C5 crystal structure, it can be noticed that the
30 CYP3A4 model exhibits a good 3D similarity in the global fold than expected, since this structure counts only for one in the six-template approach. This proves that in this approach, there is no “averaging” effect, *i.e.* the mammalian structure had a decisive influence over the five bacterial (and fungus) templates. Our final fold of

CYP3A4 is very consistent with a mammalian one, despite the fact that it has been rebuilt by using the structural information contained in non-mammalian cytochromes P450.

- 5 The active site is delimited by the six substrate recognition sites (SRS) that have been first identified and described by Gotoh (Gotoh 1992) from the unique structure available in the early 1990s (P450_{cam}), and that are today commonly accepted for depicting substrate recognition by various cytochromes P450 (especially from the family 2, but extended to other P450 families). These sites are associated with the
- 10 active site and are located in the less conserved regions of the CYPs, thus possibly accounting for the various substrate specificity among P450s. When comparing our various optimized structures, it is found that SRS1 (100-125, includes helix B), SRS 2 (205-218, includes C-terminus of helix F), and SRS3 (237-249, includes N-terminus part of helix G) are located in less-defined regions, with significant
- 15 variability in spatial position (flexibility). These regions correspond also to parts of the sequence that are less well-aligned. At the opposite, the SRS4 (295-320, central part of helix D), SRS5 (363-380, C-term of helix K and β -sheet β 1-4) and SRS6 (470-490, β -sheets β 4-1 and β 4-2) are well-defined fragments of the structures. SRS4 and SRS5 segments in particular are correlated to regions in the sequence that
- 20 are unequivocally aligned.

The only model structure of CYP3A4 that has been described in the literature and that we can handle for structural comparison, is that of Szklarz and Halpert, derived

25 from a multiple-template approach (four-bacterial template) (Szklarz and Halpert 1997). Roughly, the same secondary structures are identified, but we found divergences in SRS location between their model and those derived from the present approach. SRS4 and SRS5 match well, but SRS2 is shifted (divergence in the position of helix F along the sequence), while SRS1 (helix B'), SRS3 (helix G)

30 and SRS6 (sheet β 4) are more notably displaced. The loops connecting the secondary structures of these SRS significantly disagree. These differences are likely to issue from a wrong alignment with the crystal P450 structures in the model of Szklarz and Halpert..

Example 2: Docking Strategy

5 Our aim was to obtain the different positions of the known substrates of CYP3A4 in the active site, consistent with the oxidation sites. Considering the fact that the heme-binding site is deeply buried in the protein structure, and thus the selection and the pathway of the substrates within the enzyme structure are strongly dependent on the various possibilities of structure opening, we implemented a
10 special approach more appropriate to flexible structures, hereafter referred as “restrained dynamics docking” or “soft-restrained restrained dynamics docking”. This technique employs constrained dynamics simulations, where the only constraints are heme-substrate distances. The successive steps are:

15 *Conversion of the PDB XPLOR file in PDB for SYBYL file*

The optimized structures with XPLOR (PDB format) are visualized with the SYBYL 6.6 software (Tripos Inc.), which implies a conversion of the file (atoms types correction) so as to make it compatible and exploitable in the constrained dynamics which will be performed with SYBYL.

20

Stabilisation du modèle de P450 3A généré sous XPLOR

Then, we do agregate N°1 (in the meaning of SYBYL) with all the NC_αCO atoms of the peptide backbone of the protein. The structure is relaxed with a dynamic of 10ns at 100K followed by a une minimization of 100 pas. Agregate N°1 is then
25 deleted.

We do agregate N°2 constituted of the protein C_α only. The protein relaxation is reiterated with a dynamic of 10 ns at 100K and une minimization of 100 pas. Agregate N°2 is then deleted.

30

The all protein is then relaxed with a first dynamic of 1ns at 100K, followed by a dynamic of 1ns at 200K and a dynamic of 10ns at 300K. We terminate with a minimization of 100 pas.

Restrained dynamics docking of the substrate (example: testosterone)

We do aggregate N°3 constituted of all atoms outside a sphere of 20Å around the C_α of residues constituting the heart of the B' loop. We also add hematic iron to this
5 aggregate.

The substrate is placed inside the protein, at around 30Å from the hematic iron and next to SRS1 and SRS5 sites. The substrate is placed so that the constraints between the hematic iron and the substrate backbone go between SRS1, SRS5 and SRS3. Thus, when testosterone is docking, we establish 4 distance constraints (limit below
10 3Å, above 10Å) between hematic iron and C3, C8, C10 and C13 carbones with a constrain of 2 kcal/Å on the entire structure so as to avoid to favour the approach of one part of the substrate more than the other.

We begin to perform a dynamic without constraints of the entire system at 20 K
15 during 2ns to stabilize the system, then we perform a dynamic under constraints at 20 K during 5ns. We observe that the substrate worms between SRS1, SRS3 et SRS5 to reach a position at the vicinity of hematic iron. We terminate with a dynamic without constraints at 300 K to relax the system and we realize a minimization of 1000 pas.

20

Results

We found that the testosterone molecule is positioned at the vicinity of hematic iron in such way that the C6 of testosterone be at 4.9Å of the iron, which is compatible with the hydroxylation of this compound to give 6β-hydroxy-testosterone (Figure
25 4).

Minimizations and dynamics with the SYBYL software are performed with the Tripos force field following the parameters: dielectric constant equal to 1 and distance-dependent, minimization method of POWELL, a minimum gradient of 0.05kcal.mol⁻¹.Å⁻¹, electrostatics charges calculated according to the Gasteiger-
30 Hückel method, and a NB cutoff of 8.0Å (non-bond energies). The energetic diagram of dynamic docking of testosterone is shown in Figure 5.

Claims

- 5 1. A method for designing a 3-dimentional (3-D) model of a protein, the 3-
dimensional representation of at least three family members has already been
experimentally obtained, [said 3-dimentional representation presenting
similarities], comprising the steps of:
 - a. identification of common structural blocks (CSB) among said members of said
 - 10 family,
 - b. alignment of the amino-acids primary sequence of said family members
according to said structural similarities, represented by said CSBs, in order to
obtained a first alignment,
 - c. alignment of said protein as compared on said first alignment, in order to obtain a
 - 15 second alignment, wherein:
 - i. alignment of said protein is performed in order to maximize the
amino-acids alignment between said protein and said first alignment,
when one or more consensus amino-acid exists in said aligned
structural blocs in said first alignment, and in the amino-acid
 - 20 sequence of said protein, said consensus amino-acids are anchors
of said second alignment,
 - ii. no insertion or deletion of amino-acids can be performed in the
aligned CSBs, wherein insertion or deletions are possible in non-aligned
structural blocks, if better to align the primary amino-acids sequences,
 - 25 d. definition of the atomic 3-D structure of structural blocs of said protein,
according to the 3-D structure of the blocks of said family members,
 - e. definition of the local constraints (distance and angles) for the atoms that are
not structurally determined after step d. (that are not in the conserved structural
blocks),
 - 30 f. selection of rotamers,
 - g. determination of a family of whole 3-D model structures of said protein,
taking into account said atomic 3-D structure of structural blocs obtained in step d.,
said local constraints defined in step e., and said rotamers defined in step f.,

- h. optimization of said family of 3-D models obtained in step g., by
- i. discarding sequences that present topological defects, and
 - ii. recalculating 3-D structures by taking electrostatic forces into account, and performing the method again from step c. downward, with modifications in the alignment between the primary sequence of said protein and said first alignment, when the obtained model structures do not take into account known mutations having biological effects.
2. The method of claim 1, wherein said 3-dimensional representation of family members has been obtained by crystallography or NMR.
3. The method of claim 1, wherein said alignment of said common structural blocks in step b. is performed by use of the GOK software as described in Jean et al., 1997.
4. The method of claim 1, wherein said alignment of said common structural blocks in step c. is performed by use of the GOK software as described in Jean et al., 1997.
5. The method of claim 1, wherein step d. is performed according to the following rules:
- i. at a given position, when residues are identical between all the template structures and the target sequence, the 3D coordinates of the reference residues are purely assigned to the target residue,
 - ii. When residues differ, only the coordinates of the backbone atoms are assigned ($C\alpha$), and sometimes $C\beta$ when they exist.
6. The method of claim 1, wherein said definition of local constraints in step e. is performed by analysis of the allowed regions in Ramachandran diagram.
7. The method of claim 1, wherein distances and angles are selected in step e. by the following rules:
- i. all distances for which the lower boundary was less than 8 Å.
 - ii. all the distances involving at least one side-chain atom, to preserve the spatial arrangement between CSBs
 - iii. all the distances involving atoms of any active group such as an heme group, to fix as much as possible the neighborhood of said active group, such as an iron atom.

8. The method of claim 1, wherein angular constraints are selected in step e. by the following rule:
 - i. dihedral angles ϕ and ψ of all residues located in CSBs are defined as constraints, given by the average values of corresponding ϕ , ψ angles in said family members +/- the standard deviation
9. The method of claim 1, wherein said rotamers in step f. are selected from the couples according to the tables of Dunbrack and Karplus, where the choice of rotamers of a given amino acid is guided by the most favored zones in Ramachandran χ_1 , χ_2 maps.
10. The method of claim 1, wherein said step g. is performed with the DYANA software, as described in Güntert et al, 1997.
11. The method of claim 1, wherein said optimization in step h. comprises the use of the X-Plor software, as described in A. T. Brünger, X-PLOR, version 3.1. A system for X-ray crystallography and NMR, Yale University Press, New Haven, CT (1992) and A. T. Brünger, Molecular replacement with X-PLOR: PC-refinement and free R value. In: Proceedings of the Daresbury Study Weekend on Molecular Replacement, Daresbury, United Kingdom (1992), 49-61.
12. The method of claim 1, wherein said protein is a cytochrome P450.
13. The method of claim 12, wherein said protein is cytochrome P450 3A4 (SEQ ID N° 1)
14. The method of claim 12, wherein said family members that are used for performing said first alignment are chosen from Nor, (SEQ ID N° 2), Ery F (SEQ ID N° 3), terp (SEQ ID N° 4), Cam (SEQ ID N° 5), BM3 (SEQ ID N° 6) and 2C5 (SEQ ID N° 7).
15. A model 3-D structure of a protein, obtained by the method according to claim 1.
16. The model of claim 15, wherein said protein is cytochrome P450 3A4.
17. The model of claim 16, wherein the residues C97; R104; F101; F107; F247; F303 and C376 are responsible for the recognition of the substrate at the entry site and into the active site.
18. The model of claim 16, having the three dimensional atomic coordinates of Table 1, for C- α , and the (ϕ , ψ) couples of Table 2.

19. A method for designing a protein, biological functions of which are altered, comprising:
 - a) obtaining a 3-D model of said protein by the method of claim 1,
 - b) analyzing said model of step a., and determining the amino-acids that are putatively involved in the biological functions of said protein,
 - c) changing said amino-acids by mutating the corresponding nucleotides on the nucleic acid sequence coding for said protein, in order to obtain a mutated protein having altered properties.
20. A computer-assisted method for performing restrained dynamics docking of a substrate on an enzyme, a 3-D structure of which is available, comprising the steps of
 - j. determining a force field, and independently simulating the presence of said enzyme in said force field,
 - k. minimizing the potential energy (Ep) linked to said force field of said 3-D structure, wherein the spatial position some atoms of said enzyme is fixed, and wherein the other atoms are mobile, by allowing mobility of the mobile atoms, by
 - i. simulating an increase in temperature (in order to give kinetic energy),
 - ii. and minimizing the potential energy by re-specifying the temperature as 0 Kelvin (K)
 - l. optionally repeating step b in order to obtain other Ep minima, wherein said Ep minima are such that the structure of the protein remains folded,
 - m. minimizing Ep in said force field of said 3-D structure, wherein all the atoms of the protein are mobile, by
 - i. simulating an increase in temperature (in order to give kinetic energy), and
 - ii. minimizing the potential energy by re-specifying the temperature as 0 Kelvin (K)
 - n. simulating, at 0 K the presence of said substrate next to said enzyme,
 - o. optionally generating a dynamic on said substrate and enzyme (simulating an increase in temperature, in order to allow mobility of the atoms)

- p. generating some constraints to said substrate, in order to impose that it has interaction with said enzyme,
- q. generating a dynamic on said substrate and enzyme, with said constraints imposed in step p.,
- 5 r. optionally, generating a dynamic on said substrate and enzyme without said constraints of step p.
- 21. The method of claim 20, wherein said fixed atoms in step k. are the backbone atoms N-C α -CO in the first minimization step and only C α in subsequent minimization steps.
- 10 22. The method of claim 20, wherein said kinetic energy is simulated by temperature increase to about 100 K for about 5-20 ns.
- 23. The method of claim 20, wherein said force field in step j. comprises forces linked to
 - a. the distance between atoms,
 - 15 b. the angles of valence,
 - c. the diedric angles,
 - d. the deformation with regard to plan,
 - e. the electrostatic field,
 - f. the Van der Waals forces,
 - 20 g. hydrogen bonds.
- 24. The method of claim 20, wherein said constraints in step p. are attraction constraints to force said substrate in the active site, and wherein said constraints are not prejudiced to the exact spatial conformation of the substrate in the active site.
- 25 25. The method of claim 24, wherein said constraints are final distance constraints between some atoms of said substrate and some atoms of amino-acids present in said active site.
- 26. The method of claim 20, wherein step o. is performed with a simulated temperature of between about 15 and 50 K.
- 30 27. The method of claim 20, wherein step q. is performed with a simulated temperature of between about 15 and 50 K.
- 28. The method of claim 20, wherein step r. is performed with a simulated temperature of between about 200 and 350 K.

29. The method of claim 20, wherein said enzyme is a cytochrome P450.
30. The method of claim 21, wherein said cytochrome is cytochrome P450 3A4, and said structure is the structure obtained by the method of claim 13, in particular the model structure of claim 18.
- 5 31. The method of claim 29, wherein said substrate is a small organic compound which size can range for example from MW 288 (testosterone) to MW 1203 (cyclosporine A).
32. The method of claim 31, wherein said substrate is testosterone.
- 10 33. A computer-assisted method for performing restrained dynamics docking of at least two substrates on an enzyme, a 3-D structure of which is available, comprising the steps consisting of performing the steps depicted in claim 20 with a first substrate and repeating said steps with a second substrate when the first substrate reaches an unconstrained molecular dynamic.
- 15 34. The method of claim 33, wherein the first and second substrates are the same molecule.
35. The method of claim 33, wherein the first and second substrates are different molecules.
36. The method of claim 34, wherein the first and second substrates display an
20 allosteric effect.
37. The method of claim 34, wherein the first and second substrates display a synergistic effect.
38. The method of claims 34 and 35, wherein at least one of the substrates is an inhibitor or display an inhibitor-base mechanism.
- 25 39. The method of claims 34 and 35, wherein at least one of the substrates is an agonist.
40. The method of claim 33 comprising successively repeating the steps of claim 20 with a 3rd, 4th or 5th substrate, some of them being the same or different molecules.
- 30 41. The method of claim 33, wherein said fixed atoms in step k. are the backbone atoms N-C α -CO in the first minimization step and only C α in subsequent minimization steps.

42. The method of claim 33, wherein said kinetic energy is simulated by temperature increase to about 100 K for about 5-20 ns.
43. The method of claim 33, wherein said force field in step j. comprises forces linked to
 - 5 a. the distance between atoms,
 - b. the angles of valence
 - c. the diedric angles,
 - d. the deformation with regard to plan,
 - e. the electrostatic field,
 - 10 f. the Van der Waals forces
 - g. hydrogen bonds
44. The method of claim 33, wherein said constraints in step p. are attraction constraints to force said substrate in the active site, and wherein said constraints are not prejudiced to the exact spatial conformation of the substrate in the active site.
- 15 45. The method of claim 44, wherein said constraints are final distance constraints between some atoms of said substrate and some atoms of amino-acids present in said active site.
46. The method of claim 33, wherein step o. is performed with a simulated temperature of between about 15 and 50 K.
- 20 47. The method of claim 33, wherein step q. is performed with a simulated temperature of between about 15 and 50 K.
48. The method of claim 33, wherein step r. is performed with a simulated temperature of between about 200 and 350 K.
- 25 49. The method of claim 33, wherein said enzyme is a cytochrome P450.
50. The method of claim 49, wherein said cytochrome is cytochrome P450 3A4, and said structure is the structure obtained by the method of claim 13, in particular the model structure of claim 18.
51. The method of claim 33, wherein said first and second substrates are small organic compounds which size can range from MW 288 (testosterone) to MW 1203 (cyclosporine A).
- 30 52. The method of claim 51, wherein said substrate is testosterone.

53. The use of the method according to claim 20 or 33 for screening, designing or identifying natural, unnatural substrates or substrate analogs, as well as inhibitors, activators or modulators of said enzyme.
54. The use of the method according to claim 33 or 40 for determining the effect
5 of a first substrate on a second substrate.
55. The use according to claim 54 applied to pharmaceutical products.
56. The use of the method according to claim 33 or 40 for determining the effect of a first testosterone molecule on a testosterone molecule.
57. The use of the method according to claim 33 or 40 for determining the effect
10 of a testosterone molecule on alpha-naphtoflavone.
58. The use of the method according to claim 20 to 40 for determining the oxidative modification of the substrate according to the proximity to the heme of a part of the substrate.
15
59. The oxidized or reduced molecule derived from a given substrate modified after positioning at the right distance to the heme is called metabolite
60. The use of the method according to claim 20 to 32, or 33 to 40, for
20 performing dynamic docking of the said metabolite, either in the absence or in the presence of the second substrate in the calculation.
61. The use of the method dynamic docking to compare the energy of the bound metabolite relatively to the energy of its parent substrate bound, in order to
25 determine if the exit of the given metabolite from the enzyme is favored or not.
